# 1 Part 1: Examples execution

In this part we need to execute every part of "chap3" file. By executing it we can take a brief look on the chirp signals and spectrograms and windows.

After executing every input in "chap3" file no problems was found. Different windows was tested, they close to each other, but has different impact on the signal. (Listing 1, Figure 1).

```
1 wave = signal.make_wave(duration)
2 wave.window(np.bartlett(len(wave)))
3 spectrum = wave.make_spectrum()
4 spectrum.plot(high=880, color='red')
5 decorate(xlabel='Frequency (Hz)')
6
7 wave = signal.make_wave(duration)
8 wave.window(np.blackman(len(wave)))
9 spectrum = wave.make_spectrum()
10 spectrum.plot( high=880, color = 'green')
11 decorate(xlabel = 'Frequency (Hz)')
12
13 wave = signal.make_wave(duration)
14 wave.window(np.kaiser(len(wave), 10))
15 spectrum = wave.make_spectrum()
16 spectrum.plot(high =880, color = 'blue')
17 decorate(xlabel = 'Frequency (Hz)')
18
19 wave = signal.make_wave(duration)
20 wave.window(np.hanning(len(wave)))
21 spectrum = wave.make_spectrum()
22 spectrum.plot(high =880, color = '#FF00FF')
23 decorate(xlabel = 'Frequency (Hz)')
24
```

Listing 1: Windows computation

Figure 1: Different windows

## 2 Part 2: SawtoothChirp

In this part we need to create a SawtoothChirp class, that extends the Chirp class and provides an evaluate function. After it's done we can create its spectrogram.

Let's declare a class (Listing 2)

```

1  from thinkdsp import *
2  import numpy as np
3
4  class SawtoothChirp(Chirp):
5      def evaluate(self, ts):
6          # freq change
7          freqs = np.linspace(self.start, self.end, len(ts) - 1)
8          # steps
9          dts = np.diff(ts)
10         dphis = PI2 * freqs * dts
11         phases = np.cumsum(dphis)
12         # apply default sawtooth code
13         cycles = phases / PI2
14         frac, _ = np.modf(cycles)
15         ys = normalize(unbias(frac), self.amp)
16         return ys
17

```

Listing 2: Sawtooth class definition

Next, we can check if our class works correctly (Listing 3, Figure 2).

```
1 sawtooth = SawtoothSignal()
2 sawtooth_wave = sawtooth.make_wave(sawtooth.period * 3, framerate=40000)
3 sawtooth_wave.plot()
4 decorate(xlabel='Time (s)')
5
```

Listing 3: Sawtooth wave plot code

Figure 2: Sawtooth's wave's plot

Next, spectrogram for created signal was created (Listing 4, Figure 3).

```
1 s = wave.make_spectrogram(256)
2 s.plot()
3 decorate(xlabel='Time (s)', ylabel='Frequency (Hz)')
4
```

Listing 4: Sawtooth's spectrum computation

Figure 3: Sawtooth's spectrogram

### 3 Part 3: Changing Sawtooth

In this part we need to explore the aliasing effect on the Sawtooth chirp.

To reproduce this effect let's create a sawtooth chirp of frequency 2500 Hz to 3000 Hz and framerate of 20000 Hz (Listing 5, Figure 4). We can clearly see wide main frequency components and a lot of noise. It happens because main components and alias components are "drifting" to the higher frequency with the time, and spectrum shows overall spectrum of the sound. We can make spectrogram clearer, by increasing the wave's framerate (Figure 5).

```
1 wave = SquareSignal(1100).make_wave(duration=9.6, framerate=10000)
2 wave_clear = SquareSignal(1100).make_wave(duration=1, framerate=96000)
3 wave.make_spectrum().plot(color='red')
4 wave_clear.make_spectrum().plot(color='blue')
5
```

Listing 5: Waves creation

Figure 4: Aliasing effect

Figure 5: Aliasing effect comparison

By listening them, we can clearly notice the difference: aliased signal is more "dirty" and "noisy".

## 4 Part 4: Glissando

In this part we need to explore glissando - transition between 2 frequencies. As it was in the Lab1, Halzion track was used.

I've selected a vowel "a" transition segment on 73 second of the record.D

Code of this part - Listing 6

```
1 wave = read_wave('sound/halzion.wav')
2 segment = wave.segment(start=73.5, duration=1.5)
3 #segment.plot()
4 spec = segment.make_spectrum()
5 spec.plot(high = 5000)
6 segment.make_spectrogram(1024).plot(high=5000)
7 decorate(xlabel='Time (s)', ylabel='Frequency (Hz)')
8
```

Listing 6: HS operations

Spectrum of the signal looks fine (Figure ??), as well as spectrogram does (Figure 7. We can clearly see transition of the pitch.

Figure 6: Spectrum of a segment

Figure 7: Spectrogram of the segment

## 5 Part 5: TromboneGliss

In this part we need to create a class, that provides trombone behavior. It should provide evaluate function, that behaves like trombone would behave by sliding its tube.

### Code of the class - Listing 7

```
1 class TromboneGliss(Chirp):
2     def evaluate(self, ts):
3         l1, l2 = 1.0 / self.start, 1.0 / self.end
4         lengths = np.linspace(l1, l2, len(ts) - 1)
5         freqs = 1 / lengths
6
7         dts = np.diff(ts)
8         dphis = PI2 * freqs * dts
9         phases = np.cumsum(dphis)
10        ys = self.amp * np.cos(phases)
11        return ys
12
```

### Listing 7: Definition of the class

### Code of plotting: Listing 8.

```
1 wave1 = MyTromboneGliss(262, 349).make_wave(duration=1)
2 wave2 = MyTromboneGliss(349, 262).make_wave(duration=1)
3 wave1.apodize(); wave2.apodize()
4 wave = wave1 | wave2
5 wave.make_spectrogram(1024).plot(high=600)
6 decorate(xlabel='Time (s)', ylabel='Frequency (Hz)')
7 wave.make_audio()
8
```

### Listing 8: Class usage

As we can see, spectrogram is correct and it looks like exponential one.

Figure 8: Trombone's spectrogram

## 6 Part 6: Vowels analyze

In this part we need to make an analysis of vowels. To do it, I used Japanese vowels A I U E O - all their vowels.

Code of spectrogram plotting can be observed on the Listing 9.

```
1 wave = read_wave('sound/aiueo.wav')
2 segment = wave.segment(start=0, duration=6)
3 segment.make_spectrogram(3000).plot(high=1500)
4 decorate(xlabel='Time (s)', ylabel='Frequency (Hz)')
5
```

Listing 9: Signal and spectrum creation

As we can see on the Figure 9, Japanese vowels are differs a lot an we can easily say what the sound it is by looking on the spectrogram.

Figure 9: Spectrum of the signal

## 7 Conclusion

More advanced skills and knowledge of signals, waves spectrum and spectrogram was acquired. Spectrum is a good way to visualize a periodic signal, but we cannot use it for the non-periodic signals. But we can split the non-periodic signal into the set of small segments, which we can considered to be a periodic signals (just like it is done with integrals). That allows us to create spectrogram - a set of spectrums at any of the sound. However, we cannot achieve a good time resolution and a good frequency resolution on the same time.
